Symbolic variables

The **sym** function

x=sym('x') creates symbolic variable **x** for **x**

a=sym('alpha') creates symbolic variable **a** for **alpha**

pi=sym('pi') creates symbolic variable **pi** for **π**

s=sym('sqrt(2)') creates symbolic variable **s** for **$\sqrt{2}$**

e=sym('exp(1)') creates symbolic variable **e** for **e**

delta=sym(0.001) creates the symbolic number **delta** for
0.001=1/1000

The **syms** function

syms creates symbolic variables (like **sym**) but does not display the results in the command window.

It is very convenient when we have to define a number of symbolic variables.

For example

```
>> syms alpha beta gamma
```

is equivalent to

```
>> alpha=sym('alpha'); beta=sym('beta'); gamma=sym('gamma');
```

The **sym** function

A symbolic variable may correspond to a **symbolic expression** like

```
>> b=sym('2*k*pi*x/R')  
b =  
2*k*pi*x/R
```

or a **symbolic function** like

```
>> y=sym('3*x^2*sin(x)')  
y =  
3*x^2*sin(x)
```

or a **symbolic equation** like

```
>> Elaw=sym('E = m*c^2')  
Elaw =  
E=m*c^2
```

The **sym** function

sym can be called with a second input argument defining the type of the symbolic variable:

Command	Result
x=sym('x','real')	x is real
x=sym('x','positive')	x is positive
x=sym('x','unreal')	x is a formal variable

>> syms x y z positive

Is equivalent

>> x=sym('x','positive'); y=sym('y','positive') z=sym('z','positive');

Example 1

```
>> syms x y  
>>  
>> f=x^2+x-5*x+6-4  
f =  
x^2 - 4*x + 2  
>>  
>>  
>> g=(x+y)^2-x/y  
g =  
(x + y)^2 - x/y  
>> pretty(g)
```

$$(x + y)^2 - \frac{x}{y}$$

Simplification!

Pretty form!

Example 2

```
>> syms a b  
>> A=[a b; b a]  
A =  
[ a, b]  
[ b, a]  
  
>> det(A)  
ans =  
a^2 - b^2  
  
>> eig(A)  
ans =  
a + b  
a - b  
>>
```

← Determinant in symbolic form.

← Eigenvalues

The **subs** function

subs substitutes the current value(s) of symbolic variable(s) in a given symbolic expression.

Example:

$$y = ae^x + be^{-x}$$

```
>> syms a b x  
>> y=a*exp(x)+b*exp(-x)  
y =  
a*exp(x) + b/exp(x)
```

If we assign a value to a, we can get the special form of y as follows:

```
>> a=2; subs(y)  
ans =  
2*exp(x) + b/exp(x)
```

The **subs** function

If the prescribed variables are 2 or more **subs** is used as follows:

subs(y, {a, b, ...} {valueofa, valueofb, ... })

or equivalently

subs(y, {a,b, ...} [valueofa, valueofb, ...])

where the 2nd and the 3rd input argument are cell arrays.

So, in our example we can type:

```
>> subs(y, {a,b}, {2,-1})
```

```
ans =
```

```
2*exp(x) - 1/exp(x)
```

```
>>
```

```
>> subs(y, {a,b}, {3,2})
```

```
ans =
```

```
2/exp(x) + 3*exp(x)
```

findsym

findsym(S) returns the symbolic variables of a symbolic expression in lexicographic order. The constants **i**, **j**, and **pi** are not variables.

findsym(S,n) returns the first n variables closer to **x** or **X**.

1)

```
>> findsym( a*x+b *z +c *w)  
ans =  
a,b,c,w,x,z  
>> findsym( a*x+b *z +c *w, 4)  
ans =  
x,w,z,c
```

2)

```
>> findsym( (x^2-a^2)/(x-a) )  
ans =  
a,x  
>> findsym( (sin(x+h)-sin(x))/h )  
ans =  
h,x  
>> findsym( pi* i + x* j +y)  
ans =  
x,y
```

help symbolic

We can see a complete list of all the symbolic functions with

>> help symbolic

Some names correspond to both non-symbolic and symbolic functions. Such an example is **diff**:

With

>> help diff

we obtain help for the non-symbolic function, whereas with

>> help sym/diff

we get help for the symbolic function.

simplify

simplify(S) tries (with a lot of success!) to simplify symbolic expression **S** in 1 step (default).

simplify(S,N) tries to simplify **S** in **N** steps.

Example 1

```
>> simplify( exp(log(x^2)) )
ans =
x^2
>>
>> simplify( cos(x)^2 + sin(x)^2 )
ans =
1
>> simplify( (x+1)*x*(x-1) )
ans =
x^3 - x
```

Example 2

We will show that

$$\begin{vmatrix} a & b+c & a^2 \\ b & a+c & b^2 \\ c & a+b & c^2 \end{vmatrix} = (a-b)(a-c)(b-c)(a+b+c)$$

```
>> syms a b c
>> A=[ a b+c a^2; b c+a b^2; c a+b c^2]
A =
[ a, b + c, a^2]
[ b, a + c, b^2]
[ c, a + b, c^2]
>> det(A)
ans =
a^3*b - a^3*c - a*b^3 + a*c^3 + b^3*c - b*c^3
>> simplify(ans)
ans =
(a - b)*(a - c)*(b - c)*(a + b + c)
```

expand

expand expands polynomials, trigonometric, exponential and logarithmic functions.

Examples

expand((x+1)^3) returns $x^3 + 3*x^2 + 3*x + 1$

expand(exp(x+y)) returns $\exp(x)*\exp(y)$

expand(sin(x+y)) returns $\cos(x)*\sin(y) + \cos(y)*\sin(x)$

expand(sinh(x+y)) returns $\cosh(x)*\sinh(y) + \cosh(y)*\sinh(x)$

Example

Compute $\sin(a+b)$, $\cos(a+b)$ and $\tan(a+b)$:

```
>> syms a b  
>> expand( sin(a+b) )  
ans =  
cos(a)*sin(b) + cos(b)*sin(a)  
>>  
>> expand( cos(a+b) )  
ans =  
cos(a)*cos(b) - sin(a)*sin(b)  
>>  
>> expand( tan(a+b) )  
ans =  
-(tan(a) + tan(b))/(tan(a)*tan(b) - 1)  
>> pretty(ans)
```

$$-\frac{\tan(a) + \tan(b)}{\tan(a) \tan(b) - 1}$$

Pretty form!

simple

simple searches for simplest form of a symbolic expression or matrix.

$$f = \tan^2\left(\frac{1}{2}\cos^{-1} x\right)x(x-1)(x+1)$$

```
>> syms x
>> f=tan(acos(x)/2)^2*x*(x-1)*(x+1)
f =
x*tanacos(x)/2)^2*(x - 1)*(x + 1)
>> simplify(f)
ans =
-x*(x - 1)^2
>> simple(f)
simplify:
-x*(x - 1)^2
radsimp:
```

..... Try with MATLAB to see the rest!

factor

factor factorizes a symbolic expression.

```
>> factor( x^3 - 6*x^2 + 11*x - 6 )
```

```
ans =
```

$$(x - 3)*(x - 1)*(x - 2)$$

```
>> factor(x^12-1)
```

```
ans =
```

$$(x - 1)*(x + 1)*(x^2 + x + 1)*(x^2 + 1)*(x^2 - x + 1)*(x^4 - x^2 + 1)$$

```
>> pretty(ans)
```

$$\begin{matrix} 2 & 2 & 2 & 4 & 2 \\ (x - 1) & (x + 1) & (x^2 + x + 1) & (x^2 + 1) & (x^2 - x + 1) & (x^4 - x^2 + 1) \end{matrix}$$

collect

collect(S,v) collects all terms of **S** as a polynomial of **v**.

collect(S) collects all terms of **S** as a polynomial of the variable determined by **findsym** (e.g. **x**)

Example

$$S = x^2 - 4x^2 \cos y + 2x \cos^2 y + 3 \cos^2 y$$

```
>> syms x y
>> S=x^2-4*x^2*cos(y)+2*x-x*(cos(y))^2+3*(cos(y))^2
S =
2*x - x*cos(y)^2 - 4*x^2*cos(y) + 3*cos(y)^2 + x^2
>>
>> collect(S)
ans =
(1 - 4*cos(y))*x^2 + (2 - cos(y)^2)*x + 3*cos(y)^2
>>
>> collect(S,cos(y))
ans =
(3 - x)*cos(y)^2 + (-4*x^2)*cos(y) + x^2 + 2*x
```

limit

`limit(F)`

$$\lim_{y \rightarrow 0} F$$

`y=findsym(F)`

`limit(F,a)`

$$\lim_{y \rightarrow a} F$$

`limit(F,x,a)`

$$\lim_{x \rightarrow a} F$$

`limit(F,x,a,'left')`

$$\lim_{x \rightarrow a^-} F$$

`limit(F,x,a,'right')`

$$\lim_{x \rightarrow a^+} F$$

Example

$$\lim_{x \rightarrow \infty} \frac{x^2 + t}{2x^2 - 2x + t^2}$$

```
>> limit( (x^2+t)/(2*x^2-2*x+t^2), inf )  
ans =  
1/2
```

$$\lim_{t \rightarrow -\infty} \frac{x^2 + t}{2x^2 - 2x + t^2}$$

```
>> limit( (x^2+t)/(2*x^2-2*x+t^2), t, -inf )  
ans =  
0
```

The **diff** function

diff(S) finds the derivative with respect to **findsym(S)**

```
>> syms x t  
>> diff(4*x^3)  
ans =  
12*x^2  
>> diff( cos(2*x) )  
ans =  
-2*sin(2*x)  
>>  
>> int( t^6 )  
ans =  
1/7*t^7  
  
>> diff(x^a,a)  
ans =  
x^a*log(x)
```

The **diff** function

diff(S,n,x) or **diff(S,n,x)** finds

$$\frac{d^n S}{dx^n}$$

Example

Find the first 4 derivatives of

$$y = \log(ax + b)$$

```
>> syms a b x  
>> for i=1:4  
    diff( log(a+b*x), i)  
end  
  
ans =  
b/(a + b*x)  
ans =  
-b^2/(a + b*x)^2  
ans =  
(2*b^3)/(a + b*x)^3  
ans =  
-(6*b^4)/(a + b*x)^4
```

The **int** function

expression	
int(f) or int(sym(f))	$\int f dx$ όπου $x = \text{findsym}(f)$
int(f,v)	$\int f dv$
int(f,a,b)	$\int_a^b f dx$ όπου $x = \text{findsym}(f)$
int(f,v,a,b)	$\int_a^b f dv$

Example 1

```
>> syms a x  
>> int( exp(a*x) )  
ans =  
exp(a*x)/a  
>> pretty(ans)
```

$$\frac{\exp(ax)}{a}$$

```
>>  
>> int( x*exp(a*x) )  
ans =  
(exp(a*x)*(a*x - 1))/a^2  
>> pretty(ans)
```

$$\frac{\exp(ax)(ax - 1)}{a^2}$$

$$\int e^{ax} dx = \frac{e^{ax}}{a}$$

$$\int xe^{ax} dx = \frac{(ax - 1)e^{ax}}{a^2}$$

Example 2

We will calculate

$$\int x \sin ax dx,$$

$$\int \frac{x dx}{x^2 - a^2} \quad \text{and}$$

$$\int x J_0(x) dx$$

```
>> int( x*sin(a*x) )
```

```
ans =
```

$$(\sin(a*x) - a*x*\cos(a*x))/a^2$$

```
>> int( x/(x^2-a^2) )
```

```
ans =
```

$$\log(x^2 - a^2)/2$$

```
>> int( x*besselj(0,x) )
```

```
ans =
```

$$x*besselj(1, x)$$

The **double** function

double returns the numerical value of a symbolic expression which may not be computed symbolically.

With

```
>> int( log(1+tan(x)), 0, pi/4 )  
ans =  
(pi*log(2))/8
```

we find that $\int_0^{\pi/4} \log(1 + \tan x) dx = \frac{\pi}{8} \log 2$

The numerical value of the integral is found as follows:

```
>> double(ans)  
ans =  
0.272198261287950
```

Example: Elliptic integral

```
>> syms x  
>> int( sqrt(2-sin(x)^2) )  
Warning: Explicit integral could not be found.  
> In sym.int at 64  
ans =  
int((2 - sin(x)^2)^(1/2), x)
```

```
>> int( sqrt(2-sin(x)^2), 0, pi )  
Warning: Explicit integral could not be found.  
> In sym.int at 64  
ans =  
int((2 - sin(x)^2)^(1/2), x = 0..pi)
```

```
>> double(ans)  
ans =  
3.820197789027712
```

$$\int \sqrt{2 - \sin^2 x} dx$$

$$\int_0^\pi \sqrt{2 - \sin^2 x} dx$$

Numerical
value

The **solve** function

solve solves either a single or a system of algebraic equations.

solve('eqn') : solve eqn wrt **findsym(eqn)**

solve('eqn',var) : solve eqn wrt var

```
>> solve(a*x+b)
```

```
ans =
```

```
-b/a
```

$$ax + b = 0$$

```
>> solve(a*x+b,a)
```

```
ans =
```

```
-b/x
```

```
>> solve('a*x+b=a+x')
```

```
ans =
```

```
(a - b)/(a - 1)
```

$$ax + b = a + x$$

Used ' ' for
this equation!

Example

$$ax^2 + bx + c = 0$$

```
>> syms a b c x  
>> y=solve(a*x^2+b*x+c)  
y =  
-(b + (b^2 - 4*a*c)^(1/2))/(2*a)  
-(b - (b^2 - 4*a*c)^(1/2))/(2*a)
```

To find the roots for given values of the parameters we use **subs**.

```
>> subs(y, {a,b,c}, [1,0,-1] )  
ans =  
-1  
 1  
>> subs(y, {a,b,c}, [1,3,2] )  
ans =  
-2  
 -1
```

Systems of algebraic equations

```
solve('eqn1','eqn2',...,'eqnN')
```

```
solve('eqn1','eqn2',...,'eqnN',var1,var2,...,varN)
```

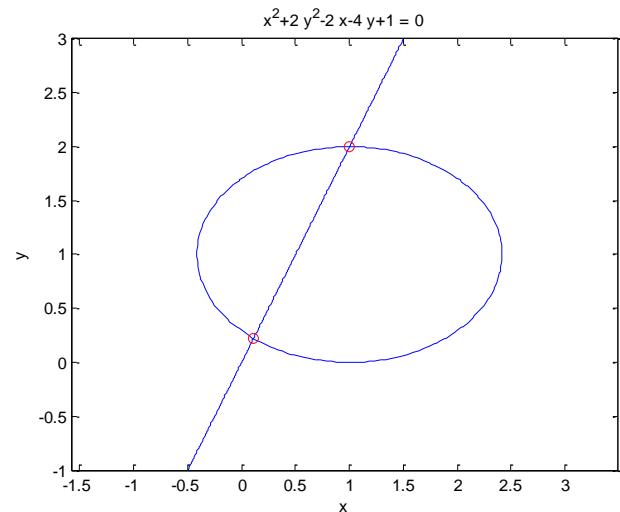

Example

Find the common points of $x^2 + 2y^2 - 2x + 4y + 1 = 0$
and $y = 2x$

```
>> [x,y]=solve('x^2+2*y^2-2*x-4*y+1','y-2*x')
```

```
x =  
1  
1/9  
y =  
2  
2/9
```

```
>> ezplot('y-2*x',[-1 3]); axis equal;  
>> set(gcf,'Color','w'); hold on  
>> ezplot('x^2+2*y^2-2*x-4*y+1')  
>> plot(subs(x),subs(y),'ro')
```

digit and vpa

When it is not possible for solve to find a symbolic solution, then it searches for a numerical solution with an accuracy of **32 digits**. This is the default value that we can see using

>> digits

We can change the accuracy to n digits using

>> digits(n)

The function **vpa** (variable precision arithmetic) calculates the value of a symbolic expression with the accuracy specified by digit.
The result is a **symbolic number**.

Example 1

With the following command we get π and e with an accuracy of 32 digits!

```
>> vpa(pi)  
ans =  
3.1415926535897932384626433832795  
>> vpa(exp(1))  
ans =  
2.7182818284590455348848081484903
```

We can change the accuracy by selecting the desired number D of accurate digits.

```
>> vpa(S,D)
```

Example 2

```
>> solve('sin(x)-x+0.1')
ans =
0.85375015664086577428139327460646
>> digits(48)
>> solve('sin(x)-x+0.1')
ans =
0.853750156640865774281393274606461525424158369061
```

Thank you!!
